**Life** is a quality that distinguishes <u>matter</u> that has <u>biological processes</u>, such as <u>signaling</u> and self-sustaining processes, from matter that does not. It is defined descriptively by the capacity for <u>homeostasis</u>, <u>organisation</u>, <u>metabolism</u>, <u>growth</u>, <u>adaptation</u>, response to <u>stimuli</u>, and <u>reproduction</u>. All life over time eventually reaches a state of <u>death</u> and none is <u>immortal</u>. Many philosophical definitions of <u>living systems</u> have been proposed, such as <u>self-organizing</u> systems. <u>Viruses</u> in particular make definition difficult as they replicate only in <u>host</u> cells. Life exists all over the Earth in air, water, and <u>soil</u>, with many <u>ecosystems</u> forming the <u>biosphere</u>. Some of these are harsh environments occupied only by <u>extremophiles</u>.
